What is an algorithm?

## Definition

An algorithm is a set of instructions or a recipe for a computer to carry out.

# Hello World

```
print 'Hello_world.'
```

```
print 'Hello_world.'  
print 4 + 5
```

algorithms

Data **types** are the building blocks from which everything else is built

- ▶ Simple Types: numbers and strings
  - ▶ numbers: 3, 12.443, 89, ...
  - ▶ strings: "hello", 'manny', "34", ...
- ▶ Complex Types: lists and dictionaries (& sets & tuples)
  - ▶ lists: [1,2,3], [1,2,"a"], ["john", "george", "paul", "ringo"], ...
  - ▶ dictionaries: {"a":1, "b":16}, ...

Python is **dynamically typed**: you do not have to declare what type each variable is

# Numbers

```
>>> 2+2
4
>>> 3/2
1
>>> 3/2.
1.5
```

Python has integers and floating point numbers (& complex numbers), and operations to convert between them:

```
>>> float(3)
3.0
>>> int(4.123)
4
```

What is a variable?

## Definition

A variable is a name that refers to some value (could be a number, a string, a list etc.)

## Example

# Variables

data types

variables

statements

Input

functions

modules

programs

strings

editing files

What is a variable?

## Definition

A variable is a name that refers to some value (could be a number, a string, a list etc.)

## Example

1. Store the value 42 in a variable named *foo*  
`foo = 42`

# Variables

algorithms

data types

variables

statements

Input

modules

programs

strings

editing files

What is a variable?

## Definition

A variable is a name that refers to some value (could be a number, a string, a list etc.)

## Example

1. Store the value 42 in a variable named *foo*  
`foo = 42`
2. Store the value of `foo+10` in a variable named *bar*  
`bar = foo + 10`

# Statements

variables

**statements**

Input

functions

modules

programs

strings

editing files

What is the difference between an expression and a statement?

## Definition

An expression *is* something, and a statement *does* something.

# User Input

[algorithms](#)[data types](#)[variables](#)[statements](#)[Input](#)[functions](#)[modules](#)[programs](#)[strings](#)[editing files](#)

## Example

1. Ask the user to input a name, and store it in the variable *name*

```
name = raw_input('enter a number:  ')
```

# User Input

algorithms

data types

variables

statements

Input

functions

modules

programs

strings

editing files

## Example

1. Ask the user to input a name, and store it in the variable

*name*

```
name = raw_input('enter a name: ')
```

2. create a new string with a greeting

```
greet = 'hello ' + name
```

# User input

[algorithms](#)[data types](#)[variables](#)[statements](#)[Input](#)[functions](#)[modules](#)[programs](#)[strings](#)[editing files](#)

## Example

1. Ask the user to input a number, and store it in the variable *foo*

```
foo = int(raw_input('enter a number: '))
```

# User input

[algorithms](#)[data types](#)[variables](#)[statements](#)[Input](#)[functions](#)[modules](#)[programs](#)[strings](#)[editing files](#)

## Example

1. Ask the user to input a number, and store it in the variable *foo*

```
foo = int(raw_input('enter a number: '))
```

2. Add *foo* and *bar* together

```
foo + bar
```

# User input

algorithms

data types

variables

statements

Input

functions

modules

programs

strings

editing files

## Example

1. Ask the user to input a number, and store it in the variable *foo*

```
foo = int(raw_input('enter a number: '))
```

2. Add *foo* and *bar* together

```
foo + bar
```

3. Calculate the average of *foo* and *bar*, and save it in a variable named *avg*

```
avg = (foo + bar)/2
```

algorithms

editing files

What is a function?

## Definition

A function is a mini-program. It can take several *arguments*, and *returns* a value.

# Modules

What is a module?

## Definition

Python is easily *extensible*. Users can easily write programs that extend the basic functionality, and these programs can be used by other programs, by loading them as a *module*

## Example

1. load the math module

```
import math
```

[algorithms](#)[data types](#)[variables](#)[statements](#)[Input](#)[functions](#)[modules](#)[programs](#)[strings](#)[editing files](#)

# Modules

What is a module?

## Definition

Python is easily *extensible*. Users can easily write programs that extend the basic functionality, and these programs can be used by other programs, by loading them as a *module*

## Example

1. load the math module  
`import math`
2. Round 35.4 to the nearest integer  
`math.round(35.4)`

# Saving and executing programs

## Example

Script File: hello.py

```
# this script prints 'hello , world ', to stdout  
print "hello ,_world"
```

Run the program:

```
python hello.py
```

# String Basics

algorithms

data types

variables

statements

Input

functions

modules

programs

**strings**

editing files

- ▶ Strings must be enclosed in quotes (double or single)
- ▶ Strings can be concatenated using the + operator

# Strings

- ▶ Many ways to write a string:

- ▶ single quotes: 'string'
- ▶ double quotes: "string"
- ▶ can also use """ to write strings over multiple lines:

```
>>> """<html>
... <body>
... something
... </body>
... </html>
... """
'<html>\n<body>\nsomething\n</body>\n</html>\n'
```

- ▶ There are string characters with special meaning: e.g.,  
\n (newline) and \t (tab)
- ▶ Get the length of a string by the len function

variables

statements

Input

functions

modules

programs

strings

editing files

## String indices & slices

You can use slices to get a part of a string

```
>>> s = "happy"
>>> len(s) # use the len function
5
>>> s[3] # indexed from 0, so 4th character
'p'
>>> s[1:3] # characters 1 and 2
'ap'
>>> s[:3] # first 3 characters
'hap'
>>> s[3:] # everything except first 3 characters
'py'
>>> s[-4] # 4th character from the back
'a'
```

# Creating/Editing Python files

Python files are simply text files, so we just need a text editor. Some options:

- ▶ Windows: Notepad or Wordpad → Save as plain text
  - ▶ Sometimes Windows is set up s.t. it forces you to add a `.txt` extension to your file.
  - ▶ This isn't a problem, but to get rid of it, (I think) you need to save as "All files" and also change your desktop settings so that they show file extensions
- ▶ Mac: TextEdit → Under *Preferences*, be sure "Plain Text" is checked for Format
- ▶ Unix: pico, Emacs (or Aquamacs [which I use]), Vim, and probably others
  - ▶ I'll focus on emacs/aquamacs this semester, but use what you like ...

# IDLE

Some text editors offer **syntax highlighting**, which shows you variable names, indentation, etc.

**Integrated Development Environments (IDEs)** offer syntax highlighting, debugging features, streamlined code-running, etc.

- ▶ One IDE which comes with Python is IDLE (<http://www.python.org/idle/doc/idlemain.html>)
  - ▶ Windows: Once you've installed Python, this should be available from Start → Applications → Python25 → ...
  - ▶ Mac: This may or may not already be installed. For me, I did the following:
    - ▶ Opened up a terminal
    - ▶ Typed:  

```
cd /System/Library/Frameworks/Python.framework/  
Versions/2.5/lib/python2.5/idlelib/
```
    - ▶ Typed: `python idle.py`

# Emacs

- ▶ emacs is a fairly basic text editor that can be run in a window or in the shell
- ▶ to start emacs:  
`emacs <filename>`
- ▶ to quit:  
`Ctrl-x Ctrl-c`
- ▶ save:  
`Ctrl-x Ctrl-s`
- ▶ search:  
`Ctrl-s`
