Language and Computers (Ling 245)

Computer-Aided Language Learning

Markus Dickinson

Department of Linguistics, Indiana University

Spring 2012
Some common computer uses

- Computers are widely used in support of foreign language teaching (FLT). For example, they
  - provide access to foreign language newspapers, radio, and TV programs through the world-wide web
  - connect language learners with native speakers through email/chat
  - support multimedia presentations providing an audio-visual foreign language context
  - enable the learner to search for real-life examples in electronic corpora

- Essentially, such computer usage helps language learners experience a foreign language and culture in a more direct, real-life fashion.
Language Tutoring Systems

Overarching question: How computers can help provide foreign language learners with experiences that are:

- richer,
- more personalized, and
- more effective?
Second language learning is very different from **first language acquisition**

- Babies & young children need no instruction
- Researchers disagree on how much of language learning ability
  - is **innate**, i.e., a biological endowment
  - **emerges** from experience, i.e., a rich social and physical environment.
First Language Acquisition

Stages of First Language Acquisition

Typical stages of first language acquisition:

- Babies play with making sounds and around six months, typical babies begin to **babble**
  - use sequences of consonants and vowels, e.g., *bababa*
- Quickly start learning words by first birthday
- Form simple 2-word utterances by the time they turn 2
- Voice & understand complex sentences by 3
- Continue acquiring words & complex language structures over next 9 or 10 years
  - Some structures, e.g., passives, added relatively late

Essentially the same pattern across all languages and cultures (with some individual variation)

A child can be a **native speaker** of multiple first languages, acquiring each of them without explicit instruction
Second Language Acquisition
Awareness of language forms

Adults do not automatically acquire a second language

▶ Even after living in a foreign country for a long time, listening to & talking in a foreign language there

▶ Research since the 90s has shown that awareness of language forms and rules is important for an adult learner to successfully acquire a foreign language.
  ▶ e.g., the use of the articles the and a in English is difficult to learn
    ▶ especially for those whose native language does not make use of articles (Chinese, Russian, etc.)
    ▶ requires awareness of: mass nouns (e.g., rice) & generics (e.g., milk in I like to drink milk)

CALL can provide an opportunity to enhance awareness of a language’s rules
Needs of second language learners

- The time a student can spend with an instructor/tutor typically is very limited
  - Work on form and grammar is often de-emphasized and confined to homework
  - The time with the instructor is used for purely communicative activities
- Learners have relatively few opportunities to gain awareness of forms & rules and receive individual feedback
The situation seems like an excellent opportunity for developing Computer-Aided Language Learning (CALL) tools to

- provide individual feedback on learner errors and
- foster learner awareness of relevant language forms and categories.

But existing CALL systems which offer exercises

- typically are limited to uncontextualized multiple choice, point-and-click, or simple form filling, and
- feedback usually is limited to yes/no or letter-by-letter matching of the string with a pre-stored answer.

Basic uses of computers for CALL

Lots of general possibilities for using a computer to learn:

▶ multimedia presentations
▶ online dictionaries with fast access
▶ extensive databases of information
▶ digital audio files
▶ digital videos of people speaking in L2
  ▶ Digital advantages: easy playback, easy isolation of problematic spots, etc.
▶ interactive games & puzzles
▶ exercises for students to complete

The last two examples potentially require sophisticated natural language processing
Basic uses of computers for CALL

Concordancers

- Take a text and create a **concordance** = display of words in context.
- Concordancers help learners understand how a given word is used.
  - For example, is the word *data* in English singular or plural?

*contract to supply voice and data communications within the Tunnel in giving control over how much data is sent over the network to the software, rather humanists to fit their special data to the software, rather 27 mm. But these data are for fourth-year crabs.*
Computers can explicitly store knowledge about words or grammar necessary to complete a specific exercise.

1. Fred lives _____ Mill Street, doesn’t he?
   - in
   - on
   - at

2. My father was born _____ Christmas Eve.
   - at
   - on
   - in

3. Come here _____ once! I need your help right now!
   - at
   - on
   - in

(Source: http://www.eslcafe.com/quiz/prep3.html)

**multiple choice exercises** work well for practicing or testing specific choices of forms or meanings.

- include so-called **distractors** as incorrect choices.
CALL systems

Fill-in-the-blank

Putting questions on the web or another computer-based platform makes it possible to provide immediate feedback.

Other possible exercises include:

- pull-down menus listing the choices
- **fill-in-the-blank (FIB)** texts: a word in a sentence is erased & the learner must type in the missing word
  - also referred to as **cloze** exercises
  - often include a **fallback case** to respond to any unexpected input
    - i.e., **canned text responses**
Early CALL systems

Frame-based systems “match student answers with a set of correct and incorrect answers stored in a frame”

- These systems differ in their strategies for selecting questions, but they rely on preset questions & answers
- In principle, could be used with NLP techniques

Many also feature a dynamic **sequencing of instruction**
Problems with frame-based systems

Frame-based systems are fairly simple and generally do not involve much linguistic knowledge

- There is no deep understanding of question domain
- They generally only match answers with questions, but language use is more varied
- There is not much tailoring to particular student needs
Language awareness
Making generalizations

What happens when teachers must specify all options for answering an exercise?

(1) Today is November 5. What date is tomorrow?
   Tomorrow is ____________________________.

Possible correct answers (among others):

- November, the sixth
- 06. 11.
- Nov., the 6th
- the sixth
- 11/06
- 6. Nov.

- Many different ways to misspell any of these options
- Many different possible incorrect answers

⇒ We need linguistic generalizations

- **named entity recognition** = identify special expressions, e.g., dates, addresses, names
Language awareness

Semantic generalizations

More broadly: refer to classes instead of individual strings

- Consider fill-in-the-blank exercise modeled on a German exercise in Trude Heift’s E-Tutor system:

(2) John works in New York City, but his family lives in Boston. On the weekend, he drives home. Fortunately, John has a new ________________.

Different options for correctly filling in this blank:

- **synonyms**: words which mean the same thing, at least in certain contexts: e.g., *car & vehicle*

- Other **lexical semantic relations** between words:
  - **hyponymy**: using a more specific term (*hyponym*), e.g., *pick-up, SUV, or hybrid car*
  - the more general term *car* is the **hypernym**
Language awareness
Morphological generalizations

Additionally, a single word in a language can show up in different forms.

▶ e.g., **citation form** or **lemma** of *bring* is *to bring*
  ▶ Also realized as *bringing*, *brought*, *bring*, or *brings*
  ▶ The different word forms and their function are investigated in **morphology**

▶ Other languages feature richer inventories of forms
  ▶ e.g., 6 forms for one of the verbs meaning *to be* in Spanish: *soy*, *eres*, *es*, *somos*, *sois*, *son*
  ▶ Plus over a dozen other tenses and moods

We would need to spell out the many different forms for each exercise in a CALL system
Language awareness

Syntactic generalizations

Consider exercises where learner can enter multiple words

- the various word order possibilities result in additional, systematic variation

- **syntax** identifies different word order possibilities & the forms words have to appear in

  (3) John, the radio is much too loud. Please ____________________!

(4) a. turn down the radio.
   b. turn the radio down.

Many non-English languages allow freer word order

- capturing all possible word orders is infeasible

Linguistic generalizations can compactly specify the expected correct or incorrect answers
Intelligent CALL (ICALL) focuses on using linguistics and natural language processing to make CALL better.

- ICALL can also involve integrating authentic text into exercises, usually for more advanced learners
- ICALL involves providing linguistic analysis to handle real learner input
Adding linguistic analysis

Tokenization

To get lemmas (or anything else), we need to find the words (or tokens)

- A text is simply a very long list of letters
- tokenization (or word segmentation) = task of finding tokens in a text

Why is this challenging?

1. **Covering ambiguity**: two or more characters may be combined to form one word or not
   - Writing systems of many languages do not use spaces between words, e.g., 要害 in Chinese:
     - Option #1: segment as two words of one character each, meaning *will hurt*
     - Option #2: segment it as a single word of two characters, meaning *vitals*
   - Context determines the segmentation

unknown words constitute a second source of difficulty for Chinese word segmentation. These are words that are not registered in the dictionary used by the word segmenter and/or are not found in the training data used to train the segmenter. While the size and domain specificity of the dictionary and training data may well affect the proportion of unknown words in real texts, unknown words will always exist, both because any dictionary creation effort has limited resources and because new words are constantly created. Chen and Bai (1998) report that 3.11% of the words in the Sinica Corpus (Chen et al., 1996), one of the largest word-segmented and POS-tagged Chinese corpora, are not listed in the CKIP lexicon, a Chinese lexicon with over 80,000 entries used for processing the corpus. These include unknown words of the categories of noun, verb, and adjective only, but not numeric type compounds or non-Chinese words. Xue (2003) partitions the 250K-word Penn Chinese Treebank (Xue et al., 2002) into training and test sets at a rather skewed ratio of 9.5:0.5 and finds that 4% of the words in the test set are unknown. Meng and Ip (1999) partition a smaller 72K-word corpus from Tsinghua University (Bai et al., 1992) at a 9:1 ratio, and report that 13% of the words in the test set are unknown.

Most previous studies treat word segmentation and unknown word identification as two separate problems, using a mechanism to identify unknown words in a post-processing step after word segmentation is done. However, determining where word boundaries are necessarily involves understanding how characters relate to and interact with each other in context, and it is desirable to capture this dynamic interaction by integrating unknown word identification with word segmentation. Several recent studies have taken a unified approach to unknown word identification and word segmentation (e.g., Sproat et al., 1996; Xue, 2003; Gao et al., 2005). We describe a hybrid model that combines machine learning with linguistic and statistical heuristics for integrating unknown word identification with Chinese word segmentation.
Adding linguistic analysis

Tokenization (2)

2. **Overlapping ambiguity**: a given character may either combine with the previous or with the next word

- 布什在谈话中指出 (ex. from Xiaofei Lu)
- Meaning changes depending on which word the second to last character 指 is part of

> 布什 在 谈话 中 指 出
> Bush at talk middle-finger out

> 布什 在 谈话 中 指 出
> Bush at talk middle point-out
> ‘Bush pointed out in his talk’

- NB: in Chinese, only the second segmentation option is grammatical
Adding linguistic analysis

Tokenization (3)

Even for English, spaces are not exact:

- e.g., *inasmuch as* and *insofar as*, *in spite of* should be single tokens

1. **Compound nouns** such as *flu shot*:

   (5) a. I got my flu shot yesterday.

   b. I got my salary yesterday.

2. **Contractions**: e.g., *I’m*, *cannot*, or *gonna*

   - They should likely be treated on a par with *I am*, *can not*, and *going to*

Automatic tokenizers typically have long lists of known words & abbreviations, plus (finite-state) rules for subregularities
Adding linguistic analysis

POS tagging

With tokens identified, we can obtain the general classes of words we want, such as part-of-speech (POS) classes

- e.g., to support meta-linguistic feedback messages such as “The sentence you entered is missing a verb.”

Parts of-speech are labels for classes of words which behave alike ... in 3 different ways:

1. **Distribution**: linear order with respect to other tokens, i.e., the slot a word appears in.
   - e.g., for *John gave him ___ ball.*:
     - slot between *him* & *ball* is distributional slot of a determiner such as *the* or *a*
   - For automatic POS taggers, distributional information encoded as statistics about POS (*n*-gram) sequences
Adding linguistic analysis

POS tagging (2)

2. Lexical stem lookup

- Unambiguous part-of-speech (POS): e.g., *claustrophobic* is only an adjective
- Ambiguous POS: e.g., *can*
  - auxiliary: *The baby can walk*.
  - full verb: *I can tuna for a living*.
  - a noun: *Pass me that can of beer, please!*
- Words not in the lexicon: a big problem for computers
Adding linguistic analysis
POS tagging (3)

3. **Morphology** the form of words
   - Markings (e.g., *suffixes* added to stem endings) encode information only appropriate for particular POS
     - e.g., the *-ed* indicated past tense
   - **Inflectional suffixes**: information such as tense or agreement (e.g., *-s* on third person singular verbs)
   - **Derivational affixes** (e.g., *-er* turns verbs into nouns: *walk* – *walker*).
     - Automatic POS-taggers use *suffix analysis* as a fallback step
     - If a word has not been seen before, *suffix analysis* determines the most likely POS
Adding linguistic analysis

POS tagging (4)

Complication: dealing with interlanguage

Consider these sentences written by Spanish learners of English (from the NOCE corpus):

(6) a. ... to be **choiced** for a job ...
   b. RED helped him **during** he was in the prison.

- **choiced**:
  - distributionally appears in a verbal slot
  - morphologically carries verbal inflection (’-ed’)
  - lexically the stem *choice* is a noun (or adjective)

- **during**:
  - morphologically is a preposition
  - distributionally a conjunction

POS tagging for learner language need to be extended to take into account such potentially mismatching evidence.
Parser-Based ICALL systems generally fall along the following lines:

- System presents the learner with an exercise
- Learner inputs an answer, possibly with errors, i.e., a potentially **ill-formed** sentence
- The parser processes this sentence
  - Identifying where, if at all, it was incorrect
  - The nature of the error
- Feedback is then presented to the student

We’ll look at two example systems:

- e-Tutor (German Tutor): Heift & Nicholson
- TAGARELA: Amaral & Meurers
Parser-Based ICALL

Detecting errors

Parsers, morphological analyzers, etc. are designed to handle well-formed input

How do we adapt technology to find errors?

- Use so-called **mal-rules** = rules which are added to your grammar that handle error cases.
  - e.g., A singular noun and a plural verb are allowed to combine, but it is marked as an error.
  - $S_{error} \rightarrow NP_{sg} \ VP_{pl}$

- Modify your technology: a parser can be reworked to handle ill-formed input.
  - Parsers normally just “die” when handling bad input.
  - e.g., I’ll parse *John are big*, but I’ll tell you that I didn’t like it and where it went wrong.
e-Tutor (German Tutor)

e-Tutor (Heft & Nicholson 2001) is used at Simon Fraser University to teach German to students; it is:

- general, i.e., allows for any native language (L1)
- able to capture different kinds of errors . . . because the exercises are very constrained

Student input is put through the following modules and stops with feedback when the first error is encountered

1. String match: if the input matches a pre-defined correct answer, we know it’s good.
   - Prevents time-consuming analysis for perfect answers

2. Punctuation check: is any punctuation missing?
More on system architecture

3. Spell check: run an off-the-shelf spell checker on the input and get the **lemmas**
   - Idea: eliminate the really basic errors.
   - Problem: sometimes a “misspelled” word is a sign of lack of grammatical competence, e.g. *runned*

4. Example check: are the right words being used?

5. Missing word check: are any words missing?

6. Extra word check: are any words added?
   - These 3 steps (example, missing word, and extra word checks) all are based on the notion that the exercise has *pre-defined* all the acceptable words.
More on system architecture (cont.)

7. Word order check: match the user word order with the correct word order

8. Grammar check
   ▶ This is the most complicated part of the process, the one which requires linguistic knowledge (syntax)
   ▶ About 60% of errors make it to this stage.

9. Catch-all: just in case everything else fails

Note:
▶ Heift’s system works so well because the exercises themselves are constrained, as we will see
▶ The approach is very modular = each check is an independent program
e-Tutor

Build a Sentence

Use all the given words (lemmas) and create a grammatical German sentence.

Advanced learner output here: “There is an error in gender with the subject.”
TAGARELA is a system for individualized instruction of Portuguese at Ohio State

- It features standard exercises, as found in foreign language workbooks
- NLP processing is used to detect spelling, morphological, syntactic, and semantic errors
- A student model is kept to track performance and to choose appropriate feedback
  - An instruction model allows the instructor to state what is important
TAGARELA system overview

INPUT

Expert Model
- Segmentation model of language
- Non-word spell check
- Shallow Parser
- Deep Processing
- Lexical look-up/Morpho analysis
- Lexicon

Analysis Manager
- Form Analysis
- Content Analysis

Instruction Model
- Activity Info
  - Exercise requirements
  - Feedback requirements
- Error Info
  - Error Taxonomy (E.T.)
  - E.T. and feedback

Student Model
- Student info
  - Name, gender, level, etc
- Grammatical competence
  - Performance by knowledge units
- Strategic competence
  - Performance by task environment

OUTPUT

Feedback Manager (pedagogical modules)
- Feedback Generation
- Error Filtering
- Ranking

ANOTATED INPUT

Content modules
- correct answer
- required words
- required stems
- WN module

Tokenizer

Feedback
- Student analysis
- Feedback selection

Segmentation model of language

Deep Processing

Shallow Parser

Lexical look-up/Morpho analysis

Lexicon

Content modules
- correct answer
- required words
- required stems
- WN module
Demand-driven architecture

Different from the e-Tutor, TAGARELA works in a demand-driven fashion; the analysis manager:

- receives input from the student
- gather the necessary information from:
  - instruction model
  - student model
- decides on the best processing strategy
  - which NLP modules to call
  - in which order (as opposed to linearly)
- calls NLP modules to process input, producing an input annotated with linguistic properties
- hands the annotated input to the feedback manager
Sources of information for CALL systems

Generally, we have 3 sources of information by which to analyze a learner production:

1. Language/linguistic properties
   ▶ General information we already discussed about linguistic generalizations

2. Exercise information
   ▶ e.g., what is known about errors for “build a sentence” exercises

3. Information about the learner ...
Modeling the learner

**Learner modeling** includes 2 types of information:

1. Learner properties which are more or less permanent
   - e.g., gender, native language, learning style
2. Dynamic record of learner performance so far: whether a learner successfully used particular words/structures

Both types of information are relevant for feedback

- e.g., native language (L1) of a learner influences words & constructions used & mistakes made
  - Positive and negative **L1-transfer**
  - Negative transfer: many native speakers of languages such as Chinese or Czech, find *the* & *a* difficult
    - L1s do not include articles of the kind found in English
    - Tutoring system should provide feedback on article misuse for learners with such native languages
How do we obtain dynamic record of learner performance?

- The system needs to draw **inferences** from the learner’s interaction with the system.
  - Need to abstract to general linguistic properties & classes which a learner answer provides evidence for
    - e.g., whether a learner answer contained a finite verb, provided evidence for subject-verb agreement, etc.
  - After seeing answers with instances of a particular property, we can infer that the learner has mastered it
    - e.g., dePrioritize feedback on it in the future

- Models may help **sequence teaching material**
  - e.g., by guiding the learner to additional material on concepts not yet mastered
Authentic Text ICALL attempts to connect learners to appropriate naturally-occurring texts

- Allows students to find examples in target language related to their interests
- Allows for more exploration and something akin to “immersion”
The WERTi System

Working with English Real-Texts: An Intelligent Workbook for English

WERTi is an “intelligent automatic workbook, providing an unlimited number of activities designed to foster awareness of English grammatical forms and functions”

- Learners select a topic which fits their interests
- Webpages are returned, which learners interact to learn about, e.g., prepositions
  - Learners can choose to see prepositions in color; click on them; or fill in blanks

Crucially, the exercises are **generated** on the fly

- Pre-existing NLP technology (e.g., a POS tagger) is used to spot the relevant categories
The REAP Project
Reader-Specific Lexical Practice for Improved Reading Comprehension

In the REAP system:

- Teachers have target vocabulary items
- REAP finds appropriate texts for learners, based on their individual profile
  - Learners get individualized vocabulary practice from authentic web texts

There are several challenges in extracting text for reading

- Each extracted text is analyzed for its “syntactic features, readability, length, and the occurrence of target vocabulary”
- Information retrieval and statistical NLP techniques are used to find appropriate texts
GLOSSER facilitates dictionary look-up

- System uses lemmatization and morphological analysis
- Look-up is 100 times faster (Nerbonne 2003)
  - Otherwise very challenging for highly-inflected languages
