# Interactive programs

## Interactive programs

- ▶ we know how to output something on the screen:  
`print('Hello world.')`
- ▶ `input`:  
`input(<prompt>)`
  - ▶ returns the input from the keyboard

## Example

```
name = input( 'type _your _name: _' )
```

## Conditionals

#

Blocks &amp; indenting

truth

Else

Nested blocks

More tests

Booleans

# If statement

Write a program to: 1) ask a user to type his/her name, 2) check if the user is known, & 3) print a welcome statement

- ▶ we know how to do the first part:

```
known_users = [ 'Sandra', 'Markus' ]  
name = input( 'type your name: ' )
```

- ▶ We can check whether a person is in the list of known users:  
`name in known_users`
- ▶ But how do we tell python to print a welcome message if the name is known?

#

Blocks &amp; indenting

truth

Else

Nested blocks

More tests

Booleans

# If statement

- ▶ syntax:

```
if <test>:  
    do this
```

- ▶ full program:

```
known_users = [ 'Sandra', 'Markus' ]  
name = input( 'type your name: ' )
```

```
if name in known_users:  
    print( "Hello " + name )
```

# Blocks & indenting

## Definition

In python, blocks are created by the use of a colon, followed by an indented section of text.

```
if <test >:  
    do something  
    do another thing  
    a final thing  
do this regardless
```

# Truth values

- ▶ a test (in the if statement) corresponds to a yes/no question and can be either true or false
- ▶ the following values count as false:

False

None

0

[] (empty list)

{ } (empty dict)

'' (empty string)

() (empty tuple)

- ▶ everything else counts as true!

## Else statements

- ▶ In case the program needs to do something when the test is false, use the `else` statement
- ▶ E.g. if a user is not known, add him/her to the list

### Example

```
known_users = ['Sandra', 'Markus']  
name = input('type your name: ')  
  
if name in known_users:  
    print('Hello ' + name + '.')  
    print('It is nice to have you back.')
```

**else:**

```
    known_users.append(name)  
    print('You have been added to the list.')
```

# Elif

- ▶ if you want to check the next condition in the else case, there is a shortcut for *else if* called `elif`

## Example

```
known_users = ['Sandra', 'Markus']
name = input('type your name: ')

if name in known_users:
    print('Hello ' + name + '.')
    print('It is nice to have you back.')
elif len(name) > 20:
    print('Your name is too long!')
else:
    known_users.append(name)
    print('You have been added to the list.')
```

Interactive

#

Blocks & indenting  
truth

Else

Nested blocks

More tests

Booleans

# Nested blocks

## Example

```
known_users = ['Sandra', 'Markus']
name = input('type your name: ')

if name in known_users:
    print('Hello ' + name + '.')
    if name.startswith('Dr.'):
        print('Taking yourself seriously, huh?')
    else:
        print('You\'re my buddy.')
else:
    known_users.append(name)
    print('You have been added to the list.')
```

# More tests

<code>x == y</code>	x equals y
<code>x &lt; y</code>	x is less than y
<code>x &gt; y</code>	x is greater than y
<code>x &gt;= y</code>	x is greater than or equal to y
<code>x &lt;= y</code>	x is less than or equal to y
<code>x != y</code>	x is not equal to y
<code>x is y</code>	x is the same object as y
<code>x is not y</code>	x is not the same object as y
<code>x in y</code>	x is a member of y
<code>x not in y</code>	x is not a member of y

- ▶ Caution: = and == are different:
  - = assigns a value
  - == compares values

# Equality vs. identity

Having the same values is not the same thing as being the same object

```
>>> x = y = [1, 2, 3]
```

```
>>> z = [1, 2, 3]
```

```
>>> x == y
```

```
True
```

```
>>> x == z
```

```
True
```

```
>>> x is y
```

```
True
```

```
>>> x is z
```

```
False
```

# Booleans

## Definition

You can combine conditions with `and` and `or`, and negate with `not`

## Example

```
if 5 < x < 10 and x not in y:  
    print('x is between 5 and 10')  
    print('and is not in the list y')
```

# Short-circuit logic

Python evaluates the first part of an and/or condition and can short circuit

- ▶ If `x` in `x or y` is True, no need to evaluate both
- ▶ If `x` in `x and y` is False, no need to evaluate both

This means you can do things like:

```
if line and line.startswith('%'):
```

You can also do things like:

```
name = input('Please enter your name: ') or  
'<unknown>'
```
